# Effects of Changes in Mesh Size upon Yield Per Recruit of Cod in Division 3M

by

R. Wells Department of Fisheries and Oceans, Research and Resource Services P. O. Box 5667, St. John's, Newfoundland, Canada AlC 5X1

INTRODUCTION

Estimates are available of the percentage retention-at-age of cod from the Flemish Cap as well as yield per recruit curves for a variety of mesh sizes of manila codends. Values of yield per recruit at the  $F_{0.1}$  and  $F_{MAX}$  levels are given here.

#### MATERIALS AND RESULTS

#### SELECTION FACTORS

Serial No. N265

Holden (1971) reviewed the literature and with respect to cod summarized the experiments dealing with selection factors as in Table 1. The selection factor for double manila was about 3.47. From selection ogives for cod in Hodder (1964), the lengths at which 50% of cod were retained in double manila codends of various mesh sizes were derived and used to estimate selection factors (Table 2). The overall mean selection factor was 3.49, in excellent agreement with Holden (1971).

### YIELD PER RECRUIT

• The percent retention-at-age of cod from the Flemish Cap was derived by Wells (1979) from material presented in Hodder (1964). Average weights were calculated by the application of a length-weight relationship to the average length-at-age of cod taken in research vessel cruises in 1977-79.

Assuming a constant number of 1-year-old cod and that cod are available from age 1-19 years, yield per recruit increases at both the  $F_{0,1}$  and  $F_{MAX}$  values as the mesh size increases up to 6 inches (Table 3).

If it is assumed that only cod of age 4 and older are retained and younger cod are discarded, discards for mesh sizes less than 5 inches are substantial.

### EQUIVALENTS

It is clear from Table 1 that codends of the same mesh size but of different materials may have different selection factors. Holden (1971) further reports that, because the range of values for the percentage elongation of polyamide at the half knot breaking load was quite wide (Table 4), mean selection factors were calculated separately for those experiments in which the polyamide used had an elongation greater than 25% and for those in which it had an elongation equal to or less than this value termed polyamide A and polyamide B respectively. The mean selection factors for cod based on this division were 4.07 for polyamide A and 3.63 for polyamide B. The equivalent values for the various materials as derived in Holden (1971) for cod were as follows:

|               | 复合感觉 计 | 「朝鮮」にも | 読み合い しょ |           | 이 같은 것을 알고 있다. | 家郷語主な  | 4 |      | 그는 같은 안생     | ÿ            |

| polyester     |        |        |         | 3.        | 95             |        |   |      | 1.14         |              |
| polypropy len | 6      |        | a P     | <b>J.</b> | 0/             |        |   |      | 1.05         | A HALFERDINA |
|               |        |        |         |           | · 경험환 개성       | 梁梁 医白白 |   |      | 이 좋아하는 것     | ě.           |

An indication of the variation about the mean selection factors is given in Fig. 1 which is a copy of page 43 of Holden (1971). It would seem that the selection factors of synthetic materials are not necessarily different from that of manila.

# CONCLUSIONS

At present growth rates of cod on the Flemish Cap, increases in yield per recruit are indicated with mesh sizes up to 6 inches (152 mm) with codends of manila. The mesh size equivalent to 6 inch manila in polyamide and polyester may be about 51 inches although the variation about the mean estimates of selection factors is very wide.
