FOURTH ANNUAL MEETING - SEPTEMBER 1982

Further Considerations in Assessment of the Cod Stock in Div. 2J+3KL

by

C. A. Bishop and S. Gavaris

Fisheries Research Branch, Department of Fisheries and Oceans
P. O. Box 5667, St. John's, Newfoundland, Canada A1C 5X1

INTRODUCTION

The report of the Standing Committee on Fishery Science (STACFIS) presented at the June 1982 Scientific Council meeting (NAFO SCS Doc. 82/VI/18) indicated that advice concerning the 1983 TAC for cod in Div. 2J3KL could not be provided. Uncertainties with the data presented (SCR Doc. 82/VI/68) caused conflicting interpretations of an appropriate terminal F in 1981 and consequently advice on the 1983 TAC. Advice concerning this stock was deferred to the present meeting so that additional information from the research vessel surveys and commercial fishery might be considered. The present paper presents new material available for 1982 along with some elaboration of data presented in the previous assessment (SCR Doc. 82/VI/68).

SURVEYS

During the years 1978-80 two Can(N) research surveys were conducted each fall in Div. 2J and 3K such that one trip fished 2J3K at depths up to 400 m while the other fished depths 200 m and greater. In 1977 a survey was conducted in 2J only while in 1981 two surveys were conducted; one in 2J at all depths and the other at all depths in 3K only. In past assessments the two fall surveys were combined and the average of the two, in terms of mean number per tow, was presented. The survey data also indicated that almost all of the cod were found in depths up to 400 m. The results from surveys which fished from 100-400 m are thus presented in the paper as it was felt that they would be more representative. It was also found that in at least one year the two surveys were separated in time by at least one month and may not be strictly comparable.

Biomass and abundance estimates from the surveys for Div. 2J and 3K with the associated confidence limits are shown in Table 1-4 and Fig. 1 and 2. Figure 3 and 4 show the stratification plans on which the surveys are conducted for Div. 2J and 3K.

Surveys in Div. 3L have been conducted by a different vessel (A. T. Cameron) and in the spring (April-June). Biomass and abundance estimates from the surveys are shown in Table 5 and 6 and in Fig. 5.

Table 7-9 show the mean number per tow estimates by age for 2J, 3K and 3L from the above mentioned surveys.

Biomass estimates show considerable fluctuation but indicate a slight increasing trend in Div. 2J and 3L. Abundance figures show considerable variation as well but are without a significant trend. From the mean number per tow data it can be seen that the 1978 year-class shows considerable strength, the 1976 and 77 year-classes are weak and that the 1973, 74, and 75 year-classes dominate the remaining ages.

AGE COMPOSITION OF THE COMMERCIAL CATCH IN 1982

Age compositions of the CanN (OT) catch in 2J3KL from January to June 1982 are shown in Table 10. Per mille age compositions were available for other contries from 2J, 3K, and 3L as shown in Tables 11-13. The 1973, 74 and 75 year-classes were important in Div. 2J and 3K but less so in 3L. The 1977 and 78 year-classes gave some indication of strength in 3L.

The per mille age compositions of Can(N) inshore gears in Div. 3K and 3L for the month of July in 1982 are shown in Table 14. Landings by individual inshore gears in 1982 are not available but the total inshore catch by Can(N) for the period Jan.-July 1982 is shown in Table 15 and Fig. 6. Table 15 also shows the inshore catch by Division for the same months from 1960-81 along with total inshore catches for the year. Fig. 6 also shows the inshore catch by year for 2J3KL. Inshore age compositions for Div. 2J inshore fishery were not available but length frequencies from the August 1982 inshore fishery by gear are shown in Fig. 7.

CATCH RATE INDEX

At the June 1982 meeting of STACFIS there was concern expressed regarding an apparent change in catchability during the mid 70's. Since the catchability coefficient was derived from the catch rate index a closer examination of the catch and effort data was warranted. Data for 1962-79 was derived from NAFO (ICNAF) Statistical Bulletins. For 1980-82 data for Canada Newfoundland vessels was obtained from the Economics Branch. Catch and effort data for other countries was available from the Foreign Observer Program for 1979-82.

The data were analyzed separately by country-gear type using a multiplicative model to take into account monthly and spatial variation. The series for Spain PT-4, Portugal OT-6 and Canada-Newfoundland OT-5 show the same general features displayed by the exploitable biomass (Fig. 8), however, there is considerable variation. These country-gear types account for the bulk of the offshore catch and will be the only ones considered in subsequent analyses. It is of interest that catch rates in 1975-76 do not decline as does the exploitable biomass, particularly for the Spanish and Portuguese series. The Canadian series appears to be lagged, especially in earlier years. It should be noted that few data are available for Canadian vessels prior to 1977 and for other countries after the mid 70's.

For the purpose of increasing the information contained in an annual catch rate index the series could be combined. Examination of the monthly pattern for the individual series (Table 16) indicated that the Spanish pair trawlers did not display the same seasonality as otter trawlers. Furthermore, it appears that the increasing fishing activity in Div. 2J by the Canadian fleet altered some of the relationships in the latter years. Due to these considerations only the data for Portugal OT-6 and OT-7 and Canada-Newfoundland OT-5 were combined using a multiplicative model. The analysis was performed separately on the data for 1962-79, derived from the Statistical Bulletin, and for 1979-82, obtained from Economics Branch and the Foreign Observer Program. The latter series was scaled to the 1979 point in the first series (Fig. 9).

The resultant index agrees fairly well mid-year with exploitable biomass except for 1971-72 where the catch rate index is low and 1974-76 where the catch rate index is high. With the addition of more data for 1982 the catch rate index does not decrease relative to 1981 (Table 17) as was the case in SCR Doc. 82/VI/68. For the catch rate index series presented in SCR Doc. 82/VI/68 the data for Spanish and Portuguese vessels during 1977-79 was excluded because the catch rates seemed low. Examination of Fig. 8 suggests that these catch rates may appear low only because the catch rates for 1974-76 were relatively higher than what might be expected. In the present analysis, all data reported to NAFO by Portugal for the period 1974-79 was included. This inclusion accounts for the major differences between the series presented in SCR Doc. 82/VI/68 and the combined series presented here.

COHORT ANALYSIS

The catch at age, average weight at age and partial selection presented in SCR Document 81/VI/66 were used in cohort analyses over a range of terminal F values for 1981. A constant value of 0.2 was assumed for natural mortality. Regression analyses of the relationship between mid-year exploitable biomass and catch rate index for the periods 1962-81 and 1962-78 (Tables 18 and 19) indicated that the best fit in terms of R² and distribution of residuals was with a terminal F in 1981 of 0.15.

The years 1974 to 1976 were excluded in all regressions. The population numbers at the beginning of the year, mid year biomass, and fishing mortality from the cohort analysis with F=0.15 in 1981 are shown in Table 20. A plot of the regression between exploitable biomass and catch rate index using a terminal F of 0.15 in 1981 is shown in Fig. 10.
