# SCIENTIFIC COUNCIL MEETING - NOVEMBER 1998 

Preliminary Assessment of Shrimp (Pandalus borealis) in Davis Strait 1998 (Subareas 0+1)

by
H. Siegstad

Greenland Institute of Natural Resources
P.O. Box 570 , DK- 3900 Nuuk, Greenland.

## 1. INTRODUCTION

The shrimp stock off West Greenland is distributed to NAFO Div.0A and Subarea 1 and the entire shrimp stock is assessed as a single population. The Greenland fishery exploits the stock in Subarea 1 (Div. 1A to 1F) in offshore and inshore areas (primarily Disko Bay). The Canadian fishery has been restricted to Div. 0A since 1981. The Scientific Council recommended at its 1997 November meeting that 1998 catches be not higher than 55.000 tons and that the TAC be reduced to this level.

Two offshore fleet components, one from Canada and one from Greenland participated in the fishery. The offshore fleet has been restricted by areas and quotas since 1977. An inshore small-vessel Greenlandic fleet was unrestricted by areas and quotas until January 1997, where quota regulation was imposed. The Canadian fishery in Div. 0A is regulated by a quota based on $17 \%$ of the advised TAC of the offshore area. Canada set the effective TAC for 1998 to 8.500 tons in Div. 0A and Greenland set the effective TAC to a total of 60.729 tons ( 36.000 tons to the offshore fleet and 24.729 to the small-vessel fleet).

The following presents the preliminary assessment of the shrimp resource in Davis Strait by summarising and interpreting data from the Greenland and the Canadian fishery and research vessel surveys.

## 2. COMMERCIAL FISHERY (SCR Doc. 98/111, 113, 123)

### 2.1. History of the Fishery

Over the last 17 years, the Canadian fishery has been restricted to Div. 0A, between the international boundary to the east and the 500 m depth contour to the west. The Canadian fishery usually takes place from July to November, whereas the Greenland fishery in Subarea 1 occurs in all months (Figure 1). Overall catches in the entire stock area increased until 1992 and decreased from 1993 to 1997 (Table 1, Figure 2). Catches in 1998 are projected to be slightly below the 1997 level.

The nominal catch of shrimp in the offshore areas of Subarea land the adjacent part of Subarca 0 (Div.0A) increased from less than 1000 tons before 1972 to almost 43000 tons in 1976. The catch fluctuated thereafter, stabilised around a level of 54000 tons during 1985-88, then increased to 66000 tons in 1992 and decreased thereafter to 51 000 tons in 1997. Total catch in the offshore area for 1998 is projected to be at the 1997 level. The Canadian fishery in Div.0A amounted to about 2600 tons in 1996, decreased to 517 tons in 1997 and 875 tons has been reported up to October 1998.

Historically, the fishing grounds in Div. 1B have been the most important. Since 1989, a gradual southward movement in particular of the offshore fishery has taken place and since 1990, catches in Div. IC + ID have exceeded those from Div. 1B. The preliminary catch figures for 1998 do not suggest any significant changes in the
distribution of the fishery from 1996 to 1998 (Fig. 3). At the end of the eightics, exploitation began in Div. 1E and IF and catches from these areas now account for about $20 \%$ of the total catch. Indications of biomass distribution from the German groundfish survey (Rätz, 1997) and the Greenland trawl survey (Carlsson and Kanneworff, 1997) may suggest that the fishery is tracking a southward shift in shrimp biomass. However, development of improved trawling gear for accessing the more difficult trawling grounds in the southern areas may also be an important factor.

The West Greenland inshore shrimp fishery was elatively stable from 1972 to 1987 with estimated catches of 7000 8000 tons annually (except for 10000 tons in 1974). Inshore catches in recent years have increased to over 20500 tons in 1992, but decreased to 13500 tons in 1997. Preliminary data for 1998 (January-October) indicate inshore catches at the same level as for the same period for 1997. During the ninetics inshore catches have accounted for about $25 \%$ of the total catch in SAI.

### 2.2. Trends in fishing effort and CPUE

Catch and effort data from the shrimp fishery in 1997 and 1998 were available from fishing records from Canadian vessels in Div. 0A and from Greenland logbooks for Subarea 1.

Up to 1986, unstandardised and standardised effort showed a slight increasing trend. Effort more than doubled between 1987 and 1992, and decreased thereafter (Figure 2). The long time trend of the standardised effort is in good agreement with the unstandardised. Twin trawls introduced in 1995 on several Greenland trawlers have been accounted for in analyses of effort data.

Two standardised CPUE indexes were presented in Hvingel et al (1998) (Table 1 and Fig. 2). The standardised CPUE series including mainly female shrimp showed a declining trend in the 1990's (A-index). The preliminary index value presented in 1997 did not change appreciably by adding a complete data set of the year. The projected 1998 value is at the 1997 level. The other index represents the CPUE series of the total catch (B-index) and showed a slightly increasing trend of the 1990's. The projected 1998 value is the highest value in the 1990's.

This discrepancy in the two CPUE scries stems from the fact they largely represent two different parts of the stock for this time period. Since 1987 the catch data used in the old index version is a mix of total catch and catch of shrimp larger than 8 g , while the data in the new index is total catch only. The divergence of the two CPUE trajectories therefore suggests that the biomass or the availability of shrimp larger than $8 g$ have been reduced throughout the 1990's.

### 2.3. By-catch and discard

Logbook from the Greenland fleet reports on landed by-catch of Pandalus montagui, discards of shrimp and fish during the years 1987-98 (Table 2). Since 1995 Greenland vessels have reported annual catches of $P$. montagui in the range of about 300 to 800 tons. The reported discard of shrimp has been around $0.5 \%$ of total catch throughout the period. The recorded discard of fish showed a slightly increasing trend.

### 2.4. Biological Data

Length frequency distributions obtained by observers were available from the commercial fishery in Div. 0A during the 1996-1998 period (Fig. 7), and in Subarea 1 from 1991 to 1998 (Table 3, Fig. 6).

The proportion of older males and female in the catches in the 1990's has shown a declining trend along with an increase in the proportion of small male shrimp (Table 3). Calculated mean shrimp size caught has declined since 1991 corresponding to a mean individual reduction in weight (g) of about $30 \%$ (Fig. 5).

The standardised catch rates for most year classes indicate increasing abundance up to age $6+$, as they pass trough the fishery (Table 3, Fig. 4). Expect for the 1993-yearclass, which appeared in large numbers in the fishery at age 4 , but in reduces number at age 5 the following year. This suggests an increased mortality on the 1993-yearclass and when it is supposed to appear in the fishery as female in 1999 the abundance could be seriously reduced.

Overall sample data indicate good recruitment, but a gradual decline in the mean carapace length of shrimp taken in this fishery.

## 3. RESEARCH SURVEY DATA (SCR Doc 98/115, 118)

### 3.1. Biomass Estimate

Stratified-random trawl surveys have been conducted from 1988 in offshore areas (Subarea $1+$ Div. 0A) and from 1991 in inshore Subarea 1 (Fig. 8). Since 1992, the survey extended further to the south in Div. 1F compared to the survey coverage in 1988 to 1991. From 1994-1997, the survey has been carricd out as a two-phase survey allocating extra trawl hauls to strata with high shrimp densities. The survey in 1998 was carried out in one step only. Compared to carlier years more trawl hauls per day have been obtained and thus a better coverage of the areas: 490 km 2 per haul in 1998 compared to 650 km 2 per haul at average for the period 1988-1997.

The biomass estimate in Div. IF has exhibited very large variations between hauls and was thus determined with a very high degree of uncertainty.

The overall biomass estimate from the survey has shown good stability in both the inshore and offshore areas. The offshore estimate varies from 160 to 220 thousand tons, apart from somewhat lower value in 1991 and 1997 (Table 4, Fig. 9). Inshore in Disko Bay is an increase in total biomass indicated for the period 1993-1998 (Table 4, Fig. 10). Large variations from year to year both geographically and over depth zones are observed and may suggest that the stock is highly migratory (Fig. 11).

### 3.2. Demographic structure offshore

Overall length distribution and results from modal analysis of shrimp in the 1998-survey area show occurrence of a very abundant year-class of large males at 20 mm CL (Fig. 12a, 12b). Also abundance of the female stock component appears high. Because the biomass estimate in the offshore area is not comparable between 1998 and 1994-97 abundance-at-age is not reported.

### 3.3. Demographic structure inshore

Survey samples from the Disko area from 1995 to 1998 were reanalysed by modal analysis, and a new age-at-length structure has been derived. The new interpretation indicated occurrence of only five year-classes of males or one year-class less than in the former interpretation.

Using the new interpretation the stock composition data from the 1998 survey indicate occurrence of a dominating size group of males at 17 mm in 1997 and at 20 mm in 1998 (Fig. 13). The female component is larger than in 1997 and of the same magnitude as in 1995 and 1996.

## 4. OTHER INFORMATION

Evaluations of trawl survey (SCR Doc 98/114). A study group was formed in 1998 to evaluate the design and efficiency of the survey. The group assessed the precision of the survey estimates, the effectiveness of the present stratification, the allocation of effort within the survey area, the appropriate tow duration and the suitability of twostage sampling. The study group also recommended on future survey design and analysis. Following these recommendations the 1998 survey has reduced the tow duration to 30 minutes from the formerly used 60 minutes in about $25 \%$ of the offshore hauls in depths between 200 and 400 meters and the two-phase survey design used from 1994 to 1997 was disconnected.

An experimental survey (SCR Doc. 98/119). An experimental bottom-trawl survey for shrimp was carried out in 1997 to examine small-scale spatial structure of shrimp and fish population densities. This study showed that day-to-day variation was small, and there was a good correlation between days for all species, both overall and within transects. There was no serial correlation in catches along isobathic transects.

Production model (SCR Doc. 98/116). A logistic model of biomass dynamics was fitted to data on catch, standardised CPUE, and research survey biomass. The reliability of the conclusions was investigated by standard jackknife, omitting one year at a time from all the series of raw data. For most of the jackknife results $\mathrm{F}_{\text {MSY }}$ was estimated consistently, both MSY and $B_{\text {MSY }}$ both ranged over a factor of about $170 \%$. STACFIC concluded that further investigation of the behaviour of the model is required.

## 5. SUMMARY OF ALL INDICES

## overall variations in catches:

- overall increase from 1981 to 1992, thereafter decreased from 1992 to 1997. Catches in 1998 are expected to be at the 1997 level.

## local variation in catches:

- catches in the inshore area increased till 1992, since then inshore catches have accounted for about $25 \%$ of the total catch in SA1
- catches offshore increased from 1988-1992, decreased since
- catches in division 0A have ranged between 6,000 and 7,500 tons from 1987 to 1992, from 1993 catches has decreased

## variations in effort:

- overall increase in effort from 1987 to 1992, has decreased since
- effort increased in Div. 0A till 1992, decreased thereafter
- in Div. IE and Div. IF increasing effort since 1991 and amount to almost $25 \%$ in 1997
- minor shift in cffort allocation in inshore/offshore - the inshore fleet optimise the catch for large female after the introduction of the quota
a shift in the fishery:
- from 1987 to 1996 a southward movement of the Greenland fishery has occurred, hereafter it stabilised
trends in recent catch rates:
- standardised CPUE series for female shrimp showed a declining trend in the 1990 's
- standardised CPUE series for all shrimp (male + female) showed a slightly increasing trend in the 1990's
composition of catches:
- overall sample data indicate good recruitment, but a gradual decline in the mean carapace length of shrimp taken in this fishery

## discard of shrimp:

- level of discarding in 0Adeclined in recent years from a high of $6.5 \%$ in 1991 to $1 \%$ in 1998
- discard of shrimp has been reported to about $0,5 \%$ of total catch throughout the period 1987-98

## biomass estimates from research surveys:

- overall stability in both offshore and inshore arca
- total offshore biomass show a good stability ranging from 160 to 220 thousand tons, apart from the lower values in 1991 and 1997
- the large increase in offshore estimated biomass from 1997 to 1998 has mainly taken place in arcas W3 and W4 in depths between 200 and 400 meter
- the inshore estimated biomass for 1998 amounted to about 65,000 tons and is the highest in the time series
- in Div.0A the estimated biomass has fluctuated between 3,000 to 17,000 tons over the previous years. The estimate for 0A in 1997 and 1998 is the lowest in the time series

## demographic structure:

- offshore and inshore males: abundant yearclass of 20 mm CL - probably the 94 yearclass
- offshore and inshore females: estimated number of females was highest
- overall length distribution show a relative strong 1994 year class and recruitment of several year classes of smaller shrimp
- a very abundance yearclass of large males of 20 mm CL is the hole survey arca
- also abundance of the female stock component appears high and there is no concern for the spawning potential
- prospects of recruitment to the female group are fair in 1999 and good in 2000

## 6. STATUS OF THE RESOURCE

Indices from the commercial fishery show that the abundance of shrimp in 1989-98 was stable but lower than the high 1976-88 level. The observed decrease of shrimp abundance from 1987 to 1989 was coincident with a substantial increase in effort. Indices show that the abundance of female shrimp declined in the 1990's, however indices of total (male and female) abundance of shrimp showed a slightly increasing trend in the 1990's. The projected 1998 value for total shrimp abundance is the highest value in the 1990 's. Overall commercial sample data indicate good recruitment, but a gradual decline in the abundance of the female component over time.

The observed southward movement of the Greenland fishery from 1987 to 1996 has stabilised. The southward displacement of the fishery may be due to the fleet tracking the southward shift in the distribution of the stock.

The overall biomass estimate from the survey has shown good stability in both the inshore and offshore areas. The offshore estimate varies from 160 to 220 thousand tons, apart from somewhat lower value in 1991 and 1997. Inshore in Disko Bay is an increase in total biomass indicated for the period 1993-1998. Large variations from year to year both geographically and over depth zones are observed and may suggest that the stock is highly migratory.

The combined inputs to the assessment indicate a stable stock that, in 1999, will be able to sustain a fishery similar to that of the latest years. The fishery in 1998 will depend on the relatively strong year class of large male and as it recruit to the female component it will maintain or improve the catch rate. The presence of several year classes, recruiting to the fishable stock in coming years, further suggest that the stock will stay at a level not lower than the present for a number of years, depending on exploitation levels and environmental changes. The stability of shrimp biomass from surveys also indicates a stable stock.
