**Abstract**

Since 1995, Spain carries out a spring stratified random bottom trawl survey in Div. 3NO of the NAFO Regulatory Area. Total mean catches, biomass and mean numbers for yellowtail flounder (*Limanda ferruginea*) are presented for the period 1995-2014, for redfish (*Sebastes spp.*) for the period 1997-2014 and for witch flounder (*Glyptocephalus cynoglossus*) for the period 2002-2014. Detailed indices are presented from 2009. Yellowtail flounder indices do not show a clear trend. Biomass increased from 1997 to 1999 and then remained almost constant throughout all the period, decreasing slightly in 2014. Redfish indices oscillate greatly over time, probably because the gear does not sample adequately aggregating pelagic species. There was a sharp increase in 2009 and since then has maintained higher values than before 2009, comprising the 3N around the 90% of the total biomass in the last years. In 2014 there was a decrease in all the indices in both Divisions. Good year classes have not been registered recently. Witch flounder is very scarce and its indices show a general decreasing trend throughout the period (2002-2014) remaining at very low levels. Recruitment was quite good at the beginning of the series but very poor in recent years.

**Material and methods**

The Spanish Spring (May/June) survey in Div. 3NO of NAFO Regulatory Area was initiated by Spain in 1995. Until 2001, the survey was carried out on board the Spanish vessel C/V *Playa de Menduiña* (338 GT and 800 HP) using a *Pedreira* type bottom trawl. The R/V *Vizconde de Eza* replaced the C/V *Playa de Menduiña* in 2001, and the *Campelen 1800* was implemented as survey gear. The main specifications and geometry of these gears, their rigging profile and the net plan, and the survey technical information are described in Walsh *et al.* (2001). The survey area was stratified following the standard stratification schemes (Bishop, 1994). Set number was allocated proportionally to the area of the strata, with a minimum of two planned hauls per stratum, and trawl positions were chosen at random (Doubleday, 1981). Biomass indices were calculated by the swept area method (Cochran, 1997), assuming catchability factor of 1. Table 1 presents the number of valid tows, the depth strata covered and the dates of the total survey series. Table 2 shows the swept area and number of hauls by stratum for the last five years (2010-2014). To know the results of the rest of the years, see González-Troncoso *et al.*, 2013. More information on the calibration method can be found in González-Troncoso *et al.* (2004) and Paz *et al.* (2004).

In each haul, all the individuals caught were sorted by species and weighted. Random samples of the catch of each species were length measured (total length) to the nearest lower cm. The obtained length distribution was aggregated into 2 cm intervals (beginning with the pair number) and raised to the catch of each species.

The redfish series for total biomass and total mean catches and mean number per tow start in 1997 because sampling depth in 1995 and 1996 was shallower than 1000 meters so the data are not representative for this species. As all strata, where the yellowtail flounder is caught were well surveyed, the series for this species are presented since 1995. As calibration for witch flounder data has not been done yet, only data from 2002 to 2014 are presented. Data for yellowtail flounder and redfish were calibrated for the period 1995-2000 and no-transformed from 2002 onwards, to create a combined 1995-2014 time-series. Regarding 2001, there are both calibrated (from the former vessel) and non-transformed data (from the new vessel).

Mean catch and variance per haul, biomass and length distribution by strata are presented for each species for the last five years (2010-2014). To see the results of the rest of the years, see González-Troncoso *et al.*, 2013. Total biomass and mean catch per tow with SD and mean number per tow by year are presented for the total period series.

Figure 1 presents the maps with the distribution of the catches of the three species during the 2014 Spanish 3NO survey.

## Results

### **Yellowtail flounder**

After a moratorium between 1994 and 1997, the yellowtail flounder fishery has been under TAC. According to the Report of NAFO Scientific Council Meeting, stock size reached a minimum in the mid 1990's, but since 1994 has steadily increased and is now well above  $B_{msy}$ . There is very low risk of the stock being below  $B_{msy}$  or  $F$  being above  $F_{msy}$ . Recent recruitment appears about average (NAFO, 2014).

### **Mean Catches and Biomass**

Table 3 shows mean catch and SD per haul and stratum and Table 4 the biomass estimates by the swept area method and their SD by stratum for years 2010-2014 for yellowtail flounder. Total biomass (t) and stratified mean catch per tow (kg) and SD by year for the entire series are presented in Table 5. Table 6 presents the parameters  $a$  and  $b$  for the calculation of the length-weight relationship for years 2010-2014.

Yellowtail flounder biomass index shows no clear trend throughout the study period. It increased substantially from 1997 (9 264 t) to 1999 (197 012 t), has maintained almost constant values until 2013 (197 968 t) and then decreased slightly in 2014 (136 487 t) (Table 5; Figures 2 and 3).

### **Length Distribution**

The mean number per haul by year is presented in Table 7 and Figure 2 for 1995-2014 and Table 8 presents the same index by length, sex and year besides the sampled size and catch for the period 2010-2014. Figures 4 and 5 present these indices for the entire period. The mean numbers are in concordance with the mean catch (Figure 2). There has not been good recruitment in recent years. In Figure 4, we can follow a length modal value since the beginning of the series, but the presence of juveniles is very low. This mode can be seen until 2009 when it reached 34-35 cm, and since 2010 the mode of the length distribution was about 30-34 cm. In 2012, 2013 and 2014 the mode was at 34 cm for females, and at 30 cm for males.

### **Redfish**

There are two species of redfish that have been commercially fished in Div. 3NO; the deep-sea redfish (*Sebastodes mentella*) and the Acadian redfish (*Sebastodes fasciatus*). Due to the difficulty to distinguish the two species, the catches are usually reported by genus as "redfish" (*Sebastodes spp.*) in the commercial fishery statistics. This stock in Div. 30 has been under TAC regulation since 1974. In September 2004, the Fisheries Commission adopted an annual TAC of 20 000 t in the entire area of Div. 30. The stock appears to have increased since the early 2000s. Current fishing mortality appears low and recent recruitment is unknown. Survey indices increased or remained stable between years during the period 2009 to 2012, but both spring and autumn indices fell considerably in 2013 to below 2009 levels. Persistent and high variability in the

indices makes it difficult to reconcile year to year changes. In 3N (the stock is 3LN) a moratorium was implemented from 1998 to 2009. The fishery was reopened in 2010 with the resultant increase of catches but the perception of the stock given by the available surveys has not been altered. There is a low risk of the stock being below  $B_{msy}$ . The probability of being above  $F_{msy}$  is very low. Recent recruitment (2005-2013) appears to be above average (NAFO, 2014).

### **Mean Catches and Biomass**

Redfish mean catches and SD are presented in Table 9 and biomass in Table 10 by stratum for 2010-2014. Annual biomass and stratified mean catch and SD per haul for years 1997-2014 are presented in Table 11 by Division. The length-weight relationship parameters  $a$  and  $b$  are presented in Table 12 for years 2010-2014.

Redfish indices oscillate greatly over time, probably because the gear does not sample adequately aggregating pelagic species. They showed a quick increase from 1997 (5 947 t) to 2000 (99 226 t), followed by a sudden drop until 2002 (11 172 t), after which they have increased to the levels of the early years of the time series. The index increased nearly fivefold in 2009 (763 980 t) in comparison with 2005 (157 716 t), the second higher value of the series (Table 10; Figures 6 and 7). This was not just due to very large catches in few hauls, as redfish catch was over 1 ton in 11 of the 43 hauls in which redfish was caught. Furthermore, redfish catch was over 15 tons in three hauls. Since 2010 a decreasing trend has been observed, but the indices for these years has maintained higher values than before 2009 (Table 10; Figures 6 and 7).

Biomass and mean catch per haul and Division, the number of strata covered in each case, and the percentage of biomass in 3N respect to the total are presented in Table 11. Biomass is always larger in 3N than in 30 (Figure 8), although the percentage is very spread over the time. Since 2005, more than 83% of redfish catches have occurred in Division 3N. However, the mean catch per town is usually higher in Division 30. In 2010, mean catch per tow in 30 was almost four times higher than in 2009, whereas in 3N was lower than in 2009. Total biomass in 3NO increased, due to the increase in 3N. In 2013 the increase in the total biomass seems to be because the increase in Division 3N. In 2014, all indices decreased in both Divisions.

### **Length Distribution**

Mean number per haul by year is presented in Table 13 and Figure 6 for 1997-2014. Table 14 presents this index per length with sample size and catch for the period 2009-2014. Figures 9 and 10 show the trend of the mean abundance per tow by length class. The y-axis upper limit of Figure 10 has been changed for years 1997-2008 to see the length distribution despite the large catches registered in the period 2009-2014. The last good year class was recorded in 2004 and this cohort can be tracked until 2014. In recent years there is only a discrete presence of juveniles. The clear 18 cm mode (20 cm in 2011) in 2009 seems to be a consequence of the 2004 recruitment. In 2012 and 2013 the mode is in 20 cm and in 20-22 cm in 2014.

### **Witch flounder**

This stock occurs mainly in Div. 30, along the South-western slopes of the Grand Bank, but it seems to migrate seasonally onto the shallow banks. It has been fished mainly in winter and springtime, targeting the spawning concentrations. The Div. 3NO estimates of biomass index for the Canadian surveys, although variable, have shown a general decreasing trend from 1985 to 1998 followed by an increase from 1998 to 2003. From 2010 to 2013 the index increased to values near the series high from 1987, although the 2013 point estimate is imprecise. Recruitment (fish less than 21 cm) has been poor since 2002. The stock has increased since 2010 and is likely to be above  $B_{lim}$  since 2011, although the current status is measured with high uncertainty. Scientific Council recommended that future removals, if allowed to increase, should only increase in an adaptive, gradual manner from current catch levels (NAFO, 2014). The stock was reopened to fishery in 2015 with a very low TAC (1 000 tons).

### **Mean Catches and Biomass**

Witch flounder mean catches and SD by stratum are presented in Table 15 and biomass per stratum in Table 16 for 2010-2014. In Table 17 and Figures 11 and 12 the annual stratified mean catch per tow and biomass with SD are presented for the period 2002-2014. The length-weight relationship parameters  $a$  and  $b$  are presented in Table 18 for 2010-2014.

Witch flounder indices show a general decreasing trend throughout the period 2002-2014. Biomass fluctuated with very low values from 1 784 t in 2002 to a depressed level of 903 t in 2014. Highest values were found in 2003 (3 145 t), 2004 (3 348 t) and 2010 (3 239 t) (Table 15; Figures 11 and 12).

### **Length Distribution**

Table 19 and Figures 13 and 14 present witch flounder mean number per tow and sex by year for 2002-2014, and Table 20 the same index by length with sample size and catch for the period 2009-2014. The best recruitment events occurred in the period 2002-2005 and have been very poor since 2008. Some modes can be tracked in Figure 13, probably due to the recruitments at the beginning of the series. In 2012 and 2013 there was a quite good presence of individuals of lengths 34-42 cm, not found in 2014.
