Northern Shrimp (*Pandalus borealis*, Krøyer) from EU-Spain Bottom Trawl
Survey 2024 in NAFO Div. 3LNO

by

Casas, J.M., E. Román-Marcote and V.M. Pajón
Instituto Español de Oceanografía (CSIC), Aptdo. 1552. 36200 - Vigo. Spain.

Abstract

The Spanish Institute of Oceanography carried out in 2024 two bottom trawl surveys in the NAFO Regulatory Area in Division 3NO and 3L during the months of June, July and August respectively. The results on Northern shrimp (*Pandalus borealis*) are presented and compared with those from previous surveys from the same series. As recent years in 2024 the shrimp catch (32.347 kg.) and estimated biomass (139.84 t.) in Divisions 3NO remain between the lowest of the series. The Northern shrimp catches in 3L Division have declined from 2009, the shrimp catch (746 kg.) and biomass estimated in 2024 (4636 t.) also remain among the lowest values in the historical series.

Introduction

Northern shrimp (*Pandalus borealis* Krøyer, 1883) is a protandric, circumpolar species, discontinuously distributed in the North Atlantic and of considerable commercial importance. The greatest abundance is being in the Northwest Atlantic at latitudes above 46°N. The stock of this species in Div. 3LNO, NAFO is distributed along the entire edge of the Grand Bank, mainly in Div. 3L, at depths generally ranging from 185 to 550 metres, although historically at least 92.7% of the 3LNO shrimp biomass had been found within Division 3L. The proportion of biomass in 3LNO within the NAFO Regulatory Area (NRA), over the period 1996 – 2014, accounted for between 4 and 32.6% (Orr and Sullivan, 2014).

Since 1995, Canadian multi-species stratified random surveys have been used to estimate northern shrimp biomass and abundance indices within NAFO Div. 3LNO. In this series of surveys, Div. 3N accounts for between 0.2 and 8.1% of the total 3LNO biomass. Between 0 and 100% of the 3N biomass was located outside the 200 Nmi limit. The biomass in Division 3O accounts for less than 1% of the biomass in Div. 3LNO and only a negligible amount of the biomass in Div. 3O is beyond the 200 miles limit (Orr and Sullivan, 2014).

The fishery began in 1993 and came under TAC control in 2000. The TAC was then reduced annually until no directed fishing was implemented for 2015. The Oceanographic Spanish Institute (IEO) is conducting research cruises since 1995 in the NAFO Regulatory Area in Div. 3NO beyond Canada's EEZ. A stratified, random, bottom trawl, multi-species research sampling program was carried out to obtain abundance and biomass indices as well as other biological data for the most important commercial species present in the area. In the surveys conducted between 1995 and 2000, the catches of northern shrimp were insignificant. This could be explained by the low efficiency of the fishing gear "pedreira", with this species (Paz et al., 1995), used in those years.

Since 2001, the survey was carried out on board R/V "Vizconde de Eza" using a Campelen 1800 net (Walsh *et al.*, 2001). Despite the improvements incorporated with the new vessel and the use of a Campelen 1800 net, which is highly efficient for this species (Vazquez, 2002), total catches in 2001 were poor, i.e., 29 kg. In the following years a significant increase of the catches of northern shrimp was noted in 3NO Division where catches were higher than 300 kg. Since 2007 the catches have declined to levels next to the lowest in the historical series.

Also, since 2003 a new research survey was conducted in Division 3L as an extension of the survey carried out in 3NO (Román *et al.*, 2008). The estimated biomass in 3L Division always was very superior to that estimated in 3NO. Since 2009, the catches have declined to low levels staying in the last years between the lowest in the historical series.

This work presents data on the geographical distribution in the NAFO Regulatory Area (Div. 3LNO), on biomass, length frequencies and age structure of catches of northern shrimp on EU-Spanish bottom trawl surveys 2024.

Materials and Methods

In 2024 the EU-Spanish bottom trawl surveys were carried out in 3NO (from 13th June to 1st July) and 3L (from 8st to 27st August) following set guidelines previously established for the series of Spanish research surveys (Walsh *et al.*, 2001). These surveys took place in Div. 3NO and 3L, with a total of 113 and 94 valid hauls respectively ranging depths between 45 and 1482 m approximately. All strata were surveyed.

Shrimp samples of approximately 1.5 kg were taken to determine length frequencies. Males and females were separated with reference to the endopod of the first pleopod (Rasmussen, 1953). Following this criterion, individuals that were in the middle of a sex change were considered as females. The females were differentiated into mature and immature, following the sternal spines criteria (McCray, 1971). Ovigerous females were considered as an independent group not included within the mature females.

Individuals were measured onboard by noting the distance from the base of the eye to the posterior mid dorsal point of the carapace -CL- (Shumway *et al.*, 1985). Such measurements were made to the lower half millimetre using electronic callipers.

Furthermore, in 2024 survey some samples were frozen onboard to determine the length-weight relationship in the laboratory.

Results and Discussion

The Table 1 shows the catches, biomass and standard errors estimated by swept area method of northern shrimp from the EU-Spanish multi-species surveys, carried out by IEO Vigo from 1995-2024 (except 2020) in the NAFO Div. 3NO and from 2003-2024 in Division 3L. In the summer of 2005, 2020, 2021 and 2022 the research survey could not be carried out in Division 3L. From the year 2002 an abrupt increase with respect to earlier years occurred in 3NO Division, both in terms of catch and biomass (Diaz *et al.*, 2002). These initial data were considered with caution due to the fact that, until 2001, the "Pedreira" gear used as a sampler (Paz *et al.*, 1995) was not efficient for catching shrimp. However, although in 2001, the gear "type Pedreira" was changed for a new type "Campelen 1800" (Walsh *et al.*, 2001) with high efficiency for catching this species (Vazquez, 2002), the catches and biomass estimated stayed at low levels.

From 2002 to 2006, the increase of shrimp catches in 3NO was confirmed, in terms of the period 1995-2001. After that, in the last years the catches and estimated biomasses of shrimp have decreased markedly and they are now at levels of the beginning of the series. The estimated biomass in 2024 was around 140 t. (Figure 1).

Unlike 3NO, the estimated biomass in 3L Division showed a general upward trend from 63 647 t. in 2003 to 149 265 t. in 2008. This trend changed in 2009 with the strong decline of the biomass estimated (74 091 t, about 50% with respect to 2008) and since then the biomass decreased up to the historical minimum recorded

in 2019 (7 063 t.). In 2024 the biomass remains unchanged compared to 2023 (4 636 t.) and it still remains between the values lowest in the survey series (Figure 1).

The distribution of northern shrimp catches in the EU-Spanish trawl surveys 2024 is shown in Figure 2. As in previous years the catches in 3NO Division were residuals.

The Tables 2 and 3 show the shrimp biomass by depth strata from 1995 to 2024 surveys in 3NO Divisions and from 2003 to 2024 in 3L Division. Although it is considered that the shrimp in Div. 3LNO is distributed along the entire edge of the Grand Bank, at depths generally ranging from 51 to 300 fathoms (93-550 m.), the depth of the bulk of biomass in 3L Division was generally in depths lower than 200 ft (92% of the biomass in 2024). From 2013 to 2015 this general pattern changed and the percentage of the estimated biomass in depths lower than 200 ft decreased up to 44%, 77% and 85% of the biomass in 2013, 2014 and 2015 respectively. In 3NO the percentage of the estimated biomass in depths lower than 200 ft. varied along the years, showing a deeper distribution in 2004, 2005 and 2011 (26%, 34% and 21% respectively).

The length distribution by sex estimated in 3NO and 3L Divisions are presented in the tables 4, 5 and Figure 3. In 3NO, the main modes were around 18 mm. for males and 22.5 mm. for females; and 18 mm. for males and 21.5 mm. for females in 3L Division. In 2024 the sex ratio was different in both Divisions, showing a higher percentage of the females (81% in 3NO and 66% in 3L).

The Table 6 shows the length-weight relationship estimated in 2024 surveys by sex and maturity stage as well the parameters of the relationship, number of specimens sampled and determination coefficient R². 376 individuals were selected in 3NO Divisions, dried and weighed with a precision of 0.01g to calculate the length-weight relationship in each Division.

The MIX modal size analysis programme was used with the length distribution by sex estimated in 3L Divisions (Table 7). From the cited analysis the males presented three modes at 14.5, 18.2 and 20.6 mm. corresponding with ages 2, 3 and 4 respectively. The females showed several modes at 16.1, 18.7, 20.9, 22.6, 24.5 and 26.1 mm from ages 2 to 7 years old.
